Keywords: Distribution, *Lentibulariaceae*, Nomenclature, Portugal, Spain

Abstract: In this paper, the genus *Pinguicula* is revised in the Iberian Peninsula. The taxa studied are *P. vulgaris*, *P. nevadensis*, *P. grandiflora* subsp. *grandiflora*, *P. dertosensis*, *P. vallisneriifolia*, *P. longifolia* subsp. *longifolia*, *P. mundi*, *P. alpina* and *P. lusitanica*. Five taxa are endemic to the area studied (*P. nevadensis*, *P. dertosensis*, *P. vallisneriifolia*, *P. longifolia* subsp. *longifolia* and *P. mundi*). Two of them are confined to restricted areas: *P. nevadensis* is endemic to the Sierra Nevada (S Spain) and *P. longifolia* subsp. *longifolia* is endemic to the central Pyrenees (N Spain). Taxonomical, nomenclatural, morphological, chromosomal, biogeographical and ecological data are reported for each taxon. A new combination is proposed: *Pinguicula* Sect. *Longifolia* (CASPER) G. BLANCA, M. RUÍZ-REJÓN et R. ZAMORA.

INTRODUCTION

The genus *Pinguicula* L. (*Lentibulariaceae*) is one of the most widespread carnivorous groups, being present on all continents except Australia; in Africa it is limited to the northwest of the continent. Over 50 *Pinguicula* species have been described to date (CASPER 1966, GIVNISH 1989, JUNIPER et al. 1989). The leaves produce a sticky glandular secretion able to capture and digest small arthropods by means of a passive capture system (HESLOP-HARRISON 1978). Like most carnivorous plants, the *Pinguicula* species are restricted to nutrient-poor habitats, such as bogs and swamps, which remain sunny and moist at least during the growing season (GIVNISH 1989). Despite the rarity of such sites in the Mediterranean ecosystems, many *Pinguicula* species are known from the Mediterranean basin (CASPER 1962). In these regions, where plant growth is greatly limited by water availability, suitable habitats for the *Pinguicula* species are scattered, isolated wet areas surrounded by larger dry habitats. Thus, for example, the populations of *P. dertosensis*, a species that is endemic to the Iberian Peninsula, are separated from one another by distances of 150–400 km. *P. grandiflora* subsp. *grandiflora* is frequent in the northern third of the Peninsula, but occurs in an isolated area in southern Spain (Sierra Nevada), at a minimum distance of 550 km from the other populations (there is also a small intermediate location 450 km away in the Peñalara Massif in the Province of Madrid). *P. vallisneriifolia* is endemic to the Baetic Mountains (Southern Spain), where there is a period of severe summer drought that lasts 4–5 months; its populations are limited to small enclaves located at a considerable distance from one another, in places where

springwaters are available; if severe drought conditions persist for several consecutive summers, these populations teeter on the brink of extinction.

The isolation of the populations must have played an important role in the speciation processes involved. Since the current aridity of the Mediterranean basin has made such small, isolated populations vulnerable to extinction (ZAMORA et al. 1996), there is an urgent need for these endangered groups to be characterized taxonomically (FALK & HOLSINGER 1991, SCHEMSKE et al. 1994).

CASPER (1972) included 12 species within the flora of Europe, 7 of which are present in the Iberian Peninsula: *P. vulgaris*, *P. nevadensis*, *P. grandiflora*, *P. vallisneriifolia*, *P. longifolia*, *P. alpina* and *P. lusitanica*. An additional two new Iberian species have recently been recognized: *P. dertensis* (MATEO & CRESPO 1995) and *P. mundi* (ZAMORA et al. 1996). In our previous study (ZAMORA et al. 1996), we analyzed the morphometric, cytogenetic, RAPD, ecological and breeding-system data for two new species, *P. submediterranea* (= *P. dertensis* nom. legit.) and *P. mundi*, and the two species closest to them (*P. grandiflora* and *P. vallisneriifolia*, respectively). The taxonomical delimitation of these two new species with regard to the other remains to be clarified, together with the distribution areas of all these taxa (the populations of some of which have previously been incorrectly ascribed to other species). The objective of the present paper is to resolve these questions and thus establish the diagnostic characters for the species present in the Iberian Peninsula.

This review was carried out by means of studying the material deposited at the BC, GDA, GDAC, JACA, MA, MAF, MGC, SALA and SEV herbaria. The BBF, BM, FI and P herbaria were also consulted for typification of certain species.

KEY FOR THE IBERIAN PENINSULA SPECIES

(Note: Corolla measurements exclude the spur)

- 1a. Corolla-lobes of the lower lip emarginate; plant overwintering as a rosette **9. *P. lusitanica***
- b. Corolla-lobes of the lower lip entire to retuse; plant overwintering as a bud **2**
- 2a. Corolla white, with yellow spots; spur 2–3(–4) mm, obtuse and curved; roots stout **8. *P. alpina***
- b. Corolla violet or pinkish; spur 2.5–18 mm, acute and straight or slightly-curved; roots slender [*P. vallisneriifolia* can have white corolla, but then spur is more than 9 mm] **3**
- 3a. Corolla 9–16 mm; spur 2.5–5(–6) mm, usually under half the length of the rest of the corolla **4**
- b. Corolla 12–26 mm; spur (6–)7–18 mm, usually over half the length of the rest of the corolla **5**
- 4a. Leaves barely longer than wide **2. *P. nevadensis***
- b. Leaves distinctly longer than wide **1. *P. vulgaris***
- 5a. Leaves with involute margin; spring leaves horizontal, close to the soil; summer leaves similar to spring leaves; corolla without violet veins **6**

- b. Leaves with \pm undulate margin; spring leaves suberect to erect; summer leaves much longer than spring leaves; corolla with violet veins, sometimes weakly marked 7
- 6a. Lobes of upper lip of calyx 3–5 mm; corolla (15–)16–25(–26) mm, entirely violet, with white throat; spur (8–)10–16 mm; seed narrowly ellipsoidal 3. *P. grandiflora*
- b. Lobes of upper lip of calyx (2–)2.5–3.5 mm; corolla (12–)13–17(–18) mm, with the lower lobes coloured only in the distal half and dark violet throat; spur (6–)7–12(–13) mm; seed ovoidal 4. *P. dertensis*
- 7a. Summer leaves elliptic to obovate, slightly undulate in the margin; throat dark violet, except in the middle lobe of the lower lip 7. *P. mundi*
- b. Summer leaves ligulate to lanceolate, strongly undulate in the margin; throat white 8
- 8a. Summer leaves ligulate, acute; lobes of upper lip of calyx ovate-oblong to ovate 5. *P. vallisneriifolia*
- b. Summer leaves lanceolate to linear-lanceolate, obtuse; lobes of upper lip of calyx oblong to linear-oblong 6. *P. longifolia*

SYSTEMATICS

Pinguicula L., Sp. Pl. 17, 1753

Small insectivorous, scapose and perennial herbs, leaves in a basal rosette, simple, entire, soft and fleshy, clothed with viscid glands above. Flowers solitary, zygomorphic, on naked pedicels often covered with viscid glands, the stalks not more than twice as long as the gland. Calyx persistent, 2-lipped, the lips separated nearly to the base, with viscid glands; upper lip 3-lobed, the lower 2-lobed. Corolla 2-lipped, spurred, with a hairy and often spotted throat; upper lip 2-lobed, lower 3-lobed. Stamens 2, epipetalous. Ovary superior, bicarpelar, 1-locular, placenta free, central; style solitary, short. Fruit a capsule opening by 2 valves; seeds numerous, very small.

Type (BRITTON & BROWN 1913, HITCHCOCK & GREEN 1929): *P. vulgaris* L.

Chromosome basic number: 6, 8.

Table 1 shows the main diagnostic features of the *Pinguicula* species present in the Iberian Peninsula.

Subgen. *Pinguicula*

Roots slender. Overwintering as a bud. Flowers big. Corolla purple-violet, bluish, pinkish or rarely white, with lobes entire to retuse; spur straight or slightly curved. Capsule ovoid, of equal length or up to twice as long as the calyx.

Sect. *Pinguicula*

Leaves with involute margin; spring leaves horizontal, close to the soil; summer leaves similar in size. Corolla without violet veins.

1. *Pinguicula vulgaris* L. (Fig. 1)

P. vulgaris L., Sp. Pl. 17, 1753. Ind. loc.: "Habitat in Europae uliginosis".

Lectotype (CHEEK in JARVIS et al. 1993): LINN No. 33.1!

Description

Perennial herbs with slender roots, overwintering as a bud, without stolons. Leaves 5–9, horizontal, close to the soil, petiolate, with the margin somewhat involute; spring leaves (at anthesis) (2–)2.5–4.5(–5) × 1.2–2.4 mm, elliptic oblong or obovate-oblong; summer leaves (at fruiting) similar to spring leaves. Pedicels 1–5, (5–)6–18 cm long, glandular-pubescent. Upper lip of the calyx with lobes 2.5–3 mm long, narrowly elliptic, oblong to ovate, obtuse or subacute; lower lip lobed for 1/3–1/2 of its length. Corolla (12–)13–15(–16) mm long (spur excluded), entirely violet; upper lip with lobes oblong-obovate, obtuse; lower lip longer, with lobes 5–7.5 mm long, much longer than wide, oblong to oblong-obovate, divergent, not overlapping, obtuse or truncate, at times retuse, the middle somewhat longer; throat usually white; tube short, infundibuliform, sparsely glandular outside; spur 2.5–5(–6) mm long, cylindric-subulate, straight. Capsule 4–6 mm long, ovoid; seeds 0.8–0.9 mm long, ovate-lanceolate, reticulate.

Chromosome number

2n=64 (DOULAT 1947, LÖVE & LÖVE 1944, 1948, 1956, 1982, WOOD & GODFREY 1957, LAANE 1967, 1969, LÖVE & KJELLQVIST 1974 [using material from the Iberian Peninsula], MURÍN 1976).

Distribution

Extends throughout North America, Europe, western and central Asia, and north-west Africa (Morocco). In the Iberian Peninsula, it is dispersed in the northern third (Fig. 2), from the Serra do Geres (Portugal; cf. COUTINHO 1939, and CASPER 1962), León mountains, Cantabrian mountains and Pyrenees; the southernmost locations are in the Universales mountains of Spain (E of the Province of Teruel and NW of the Province of Cuenca).

Ecological behaviour

Peat bogs, wetlands, waterlogged pastures, banks of streams, etc. Indifferent to soil type. Altitude: 1400–2600 m. Flowering season: (V–)VI–VII(–VIII).

2. *Pinguicula nevadensis* (LINDB.) CASPER (Fig. 1)

P. nevadensis (LINDB.) CASPER, Feddes Repert. 66: 112, 1962.

≡ *P. vulgaris* subsp. *nevadensis* LINDB., Acta Soc. Sci. Fenn. 2: 142, 1932.

Holotype: Hispania, Sierra Nevada, in turfosis humidis in declivi supra Laguna de las Yeguas, c. 2600 m (22.VII.1926 LINDBERG LD).

– *P. leptoceras* auct. non RCHB. 1823: BOISS., Voy. Bot. Espagne 2: 521, 1841.

Description

Perennial herbs with slender roots, overwintering as a bud, without stolons. Leaves 5–8, horizontal, close to the soil, sessile to shortly petiolate, yellowish, with the margin more or less involute; spring leaves (at anthesis) 1.5–4.5(–5) × 0.7–2.5 cm, suborbicular to ovate, frequently little longer than wide; summer leaves (at fruiting) similar to spring leaves. Pedicels 1–3(–4), 3–10(–11) cm long, glandular-pubescent. Upper lip of the calyx with lobes 2–3 mm long, ovate to oblong-ovate, obtuse, more or less divergent; lower lip lobed for up to 1/3 of

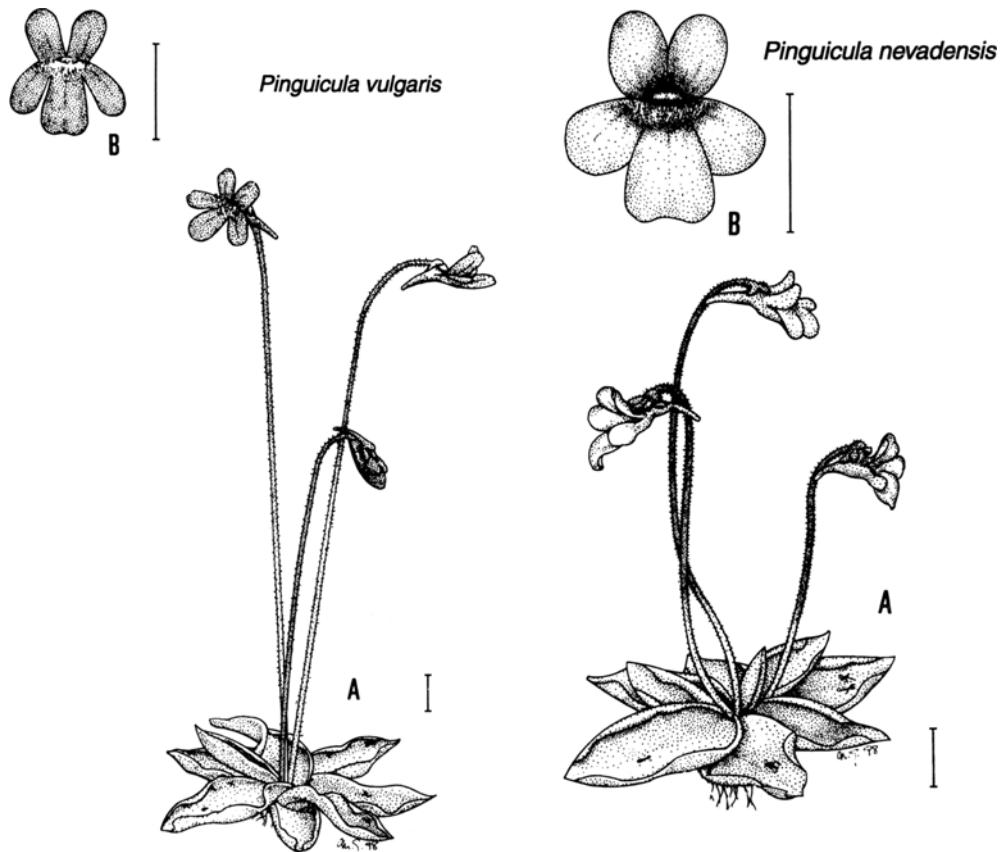

Fig. 1. *Pinguicula vulgaris* and *Pinguicula nevadensis*; A – habit, B – flower. Scale bars 1 cm.

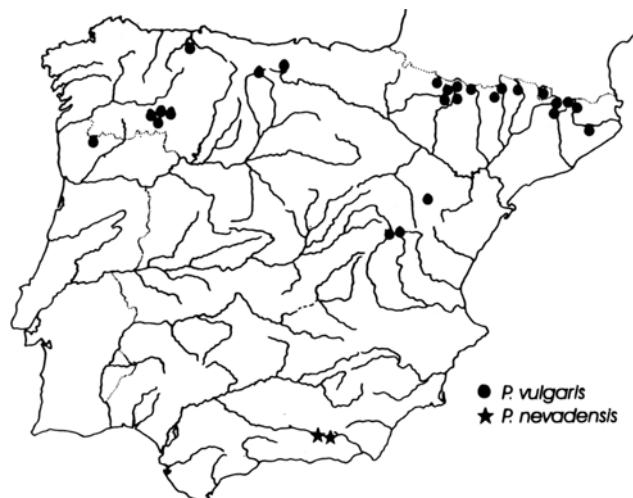

Fig. 2. Distribution map of *Pinguicula vulgaris* in the Iberian Peninsula and *P. nevadensis*.

its length. Corolla (9–)10–16 mm long (spur excluded), lilac; upper lip with lobes ovate, obtuse; lower lip with lobes (3–)4–7 mm long, obovate-oblong to broadly obovate, overlapping, obtuse, pale lilac to whitish, the middle entire to retuse; throat violet; tube short, infundibuliform, about as long as the lips, sparsely glandular outside; spur 3–5(–6) mm long, cylindric-subulate, straight or weakly-curved. Capsule 3–5 mm long, ovoid; seeds 0.7–0.8 mm long, ellipsoidal, reticulate.

Chromosome number

2n=16 (ZAMORA et al. 1996).

Distribution

Endemic to the Sierra Nevada (Province of Granada; Fig. 2). The presence of this species in the Sierra de Alfacar (Province of Granada), based on a voucher specimen of Gandojer deposited at the PRC herbarium (cf. CASPER 1962: 113), must be discounted, as it has not subsequently been found in the Alfacar mountains and the area in question does not meet the ecological requirements of the species; this report must almost certainly be due to a labelling error.

Ecological behaviour

Moist peat soils, waterlogged meadows (known locally as “borreguiles”). Silicicolous. Altitude: 2000–3100 m. Flowering season: (VI–)VII–VIII.

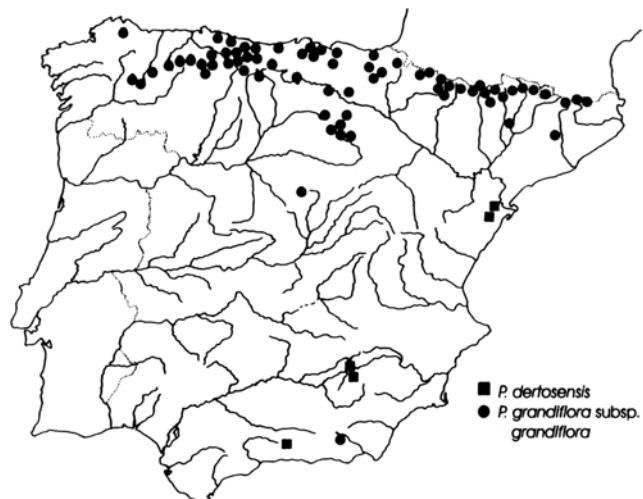

Fig. 4. Distribution map of *Pinguicula grandiflora* subsp. *grandiflora* in the Iberian Peninsula and *P. dertensis*.

Description

Perennial herbs with slender roots, overwintering as a bud, without stolons. Leaves 5–9, horizontal, close to the soil, petiolate, with the margin more or less involute; spring leaves (at anthesis) 3–6(–6.5) × 1.5–3 cm, oblong, obovate-oblong to elliptic; summer leaves (at fruiting) similar to spring leaves. Pedicels 1–5, (4.5–)6–18(–20) cm long, glandular-pubescent. Upper lip of the calyx with lobes (2.5–)3–5 mm long, oblong, elliptic or subtriangular, obtuse or subacute; lower lip lobed for up to 1/3 of its length. Corolla (15–)16–25(–26) mm long (spur excluded), entirely violet; upper lip with lobes suborbicular to obovate, obtuse; lower lip with lobes (5–)6–11 mm long, about as long as wide, suborbicular to obovate, overlapping, obtuse or truncate, at times retuse, the middle one wider; throat white, with two dark spots in the upper part, near the stigma; tube short, broadly infundibuliform, sparsely glandular outside; spur (8–)10–16 mm long, cylindric-subulate, straight, sometimes slightly bifid. Capsule (4–)5–7(–8) mm long, ovoid to subglobose; seeds 0.8–0.9 mm long, narrowly ellipsoidal, reticulate.

Chromosome number

2n=32 (DOULAT 1947, WOOD & GODFREY 1957, CONTANDRIOPoulos 1962, CASPER 1963, ZAMORA et al. 1996; the latter using material from the Iberian Peninsula).

Distribution

Western Europe (Ireland, France, Switzerland and Spain). *P. grandiflora* has two subspecies: subsp. *grandiflora*, distributed throughout the range of the species, and subsp. *rosea* (MUTEL) CASPER, in south-eastern France (Savoie), which is distinguished from subsp. *grandiflora* by the smaller size of all its parts and by the pinkish to pale lilac corolla with subulate spur. In the Iberian Peninsula, the former subspecies is distributed throughout the northern third (Fig. 4), reaching south to the Peñalara massif (Province of Madrid) and the Sierra Nevada (Province of Almería).

Ecological behaviour

Wetlands, waterlogged pastures, peat bogs, rocky banks, springs, banks of streams, etc. Indifferent to soil type. Altitude: (200–)500–2300 m. Flowering season: III–VIII.

Comments

A highly variable species, including a number of taxa of low taxonomical value. SENNEN (1936) described three new species, *P. merinoana*, *P. eliae* and *P. inaequilobata*, the latter two at the same location. The characters of the former two, as CASPER (1962) noted, coincide with those of *P. grandiflora*, whereas *P. inaequilobata* was considered to be a mere variety.

With regard to the subsp. *coenocantabrica*, the characters listed by RIVAS MARTÍNEZ et al. (1984) correspond to individuals that are bigger as a result of more favourable ecological conditions; such specimens are also to be found in other geographical areas mixed with individuals of usual size.

4. *Pinguicula dertosensis* (CAÑIG.) MATEO et M.B. CRESPO (Fig. 3)

P. dertosensis (CAÑIG.) MATEO et M.B. CRESPO, Fl. Abrev. Com. Valenciana, 1995: 430.

≡ *P. grandiflora* var. *dertosensis* CAÑIG., Collect. Bot. 5: 413, 1957.

Holotype: Puertos de Beceite, in confinibus Aragoniae et catal. pr. Font del Teix, in initio Barranc del Parrissal (IV.1935 BARTOMEUS BC 87830!).

≡ *P. grandiflora* subsp. *dertosensis* (CAÑIG.) O. BOLÓS et VIGO, Collect. Bot. 14: 99, 1983.

= *P. submediterranea* BLANCA et al., Pl. Syst. Evol. 200: 57, 1996.

Holotype: Sierra de Cazorla (Jaén provincia, Hispania), 1300 m s.m.n.m. in clivis terreis humidissimis atque muscis coopertis (10.VI.1993 R. ZAMORA GDAC 37732!).

Description

Perennial herbs with slender roots, overwintering as a bud, without stolons. Leaves 6–9(–12), horizontal, close to the soil, shortly petiolate to petiolate, with the margin more or less involute; spring leaves (at anthesis) (2–)3–7(–9) × 1.5–2.5 cm, obovate to obovate-oblong; summer leaves (at fruiting) similar to spring leaves. Pedicels 1–5, 5–13 cm long, glandular-pubescent. Upper lip of the calyx with lobes (2–)2.5–3.5 mm long, ovate-lanceolate to lanceolate, obtuse or subacute; lower lip lobed for up to 1/2 of its length or sometimes nearly to the base. Corolla (12–)13–17(–18) mm long (spur excluded), violet; upper lip dark violet, with lobes suborbicular to obovate, obtuse; lower lip with lobes 5–10 mm long, longer than wide, obovate, overlapping, obtuse, coloured only in the upper half, the middle entire to retuse, white- to yellow-spotted near the base; throat dark violet, except in the middle lobe of the lower lip; tube short, broadly infundibuliform, sparsely glandular outside; spur (6–)7–12(–13) mm long, cylindric-subulate, straight, sometimes slightly bifid. Capsule 2.5–4.6 mm long, ovoid to subglobose; seeds 0.5–0.6 mm long, ovoidal, reticulate.

Chromosome number

2n=48 (ZAMORA et al. 1996). As noted by ZAMORA et al. (1996), *P. dertosensis* very probably has an allopolyploid origin, from the crossing of a tetraploid species (2n=32, probably *P. grandiflora*, the one taxonomically closest to *P. dertosensis*) with a unknown diploid species, and the subsequent duplication of the chromosome number. Another possibility would be the result of the crossing of an octoploid species (2n=64) and a tetraploid one (2n=32); the two species involved may have been *P. vulgaris* and *P. grandiflora*, respectively. This latter possibility would be highly probable if *P. vulgaris* were an autoploid originating from *P. grandiflora*.

Distribution

Dispersed throughout the east and southeast of the Peninsula (Fig. 4), from the Tortosa (Tarragona) and Beceite (Teruel) mountain passes to the Sierra Tejeda (Granada). Its presence in the Province of Castellón was reported by AGUILELLA et al. (1992).

Ecological behaviour

Waterlogged pastures, rocky banks, banks of streams, etc. Calcicolous. Altitude: 600–1700 m. Flowering season: IV–VI(–VII).

Comments

This species was considered to be a variety of *P. grandiflora* by CAÑIGUERAL (1957). The protologue of this variety is rather confusing. The published location, "Ports de Tortosa" (Province of Tarragona) is not the same as that given on the label of the voucher specimen denominated as the holotype (BC 87830), namely, "Puertos de Beceite" (Province of Teruel), even though the two locations in fact coincide, since a single mountain pass forms the border between two Spanish regions and the pass is known by a different name in each. Furthermore, CAÑIGUERAL (1957: 413) noted in the description of the new variety that the corolla was "alba in gutture", whereas one of the most striking characters of the species is that the throat of the corolla is a dark violet colour (ZAMORA et al. 1996: 57, sub *P. submediterranea*).

The taxonomic category of the variety was upgraded to the rank of subspecies and species by BOLÓS & VIGO (1983) and MATEO & CRESPO (1995), respectively.

ZAMORA et al. (1996), having made a detailed study of several Spanish *Pinguicula* species, detected a chromosome number ($2n=48$) that differed from the number known for *P. grandiflora* ($2n=32$); this character, together with the morphological features indicated above in the identification key and the genetic isolation demonstrated by experimental hybridization, would suggest that this taxon merits consideration at species rank. Owing to the difficulties posed by CAÑIGUERAL's protologue, they opted for a new name, *P. submediterranea*, although while their article was still in press the book by MATEO & CRESPO (1995) was published, in which *P. dertosensis* was elevated to the category of species; the difference of a few months in the appearance of these two publications would give priority to the combination proposed by MATEO & CRESPO (1995).

In the southeastern Iberian Peninsula the populations of this species had been traditionally included within *P. vallisneriifolia*.

Sect. *Longifolia* (CASPER) BLANCA, M. RUÍZ REJÓN et ZAMORA, comb. et stat. nov.

≡ Ser. *Longifolia* CASPER, Feddes Repert. 66: 61, 1962.

Leaves with \pm undulate margin; spring leaves suberect to erect; summer leaves much longer. Corolla with violet veins, sometimes weakly marked.

5. *Pinguicula vallisneriifolia* WEBB (Fig. 5)

P. vallisneriifolia WEBB, Otia Hisp. ed. 2: 48, 1853.

Ind. loc.: "HAB. Hanc plantam in Baetica circa rivulorum fontes et in rupibus lapsu aquarum madidis Espumaredas dictis, non longe ab oppido Velez-el-Rubio, julio fructiferam et fere defloratam, legit anno 1851 cl. Antonius Blanco".

Lectotype (designated here): In montibus circa Velez Rubio (s.a. BLANCO FI!).

The reference to Vélez Rubio, a village in the Province of Almería (SE Spain; see Fig. 6, locality marked with "?") appears to have been an error, as studies made of the flora of this village (CUETO 1989, CUETO & BLANCA 1997) discounted the presence of *P. vallisneriifolia* in the area. Furthermore, the area called "Espumaredas" is totally unknown to the villagers; however, there is a small valley and river called "Espumaderas" in the Sierra de Cazorla (Province of Jaén), where *P. vallisneriifolia* is indeed present, which could explain the confusion. As this shows every sign of being a labelling error, the presence of this species in the Province of Almería should be discounted.

Description

Perennial herbs, with slender roots and stolons present, overwintering as a bud. Leaves suberect to erect, sessile, with prominent median nerve on the back, with the margin not involute; spring leaves (at anthesis) 5–8, 2.5–7 × 1–2(–2.5) cm, elliptic to obovate-oblong; summer leaves (at fruiting) 6–15, much longer, (5–)10–25 × (0.5–)0.7–2.5 cm, ligulate, undulate in the margins, subpetiolate, acute or subacute. Pedicels 1–8(–10), (5–)7–15(–7) cm long, glandular-pubescent. Upper lip of the calyx with lobes 3–5 mm long, ovate-oblong to ovate, obtuse or subacute; lower lip lobed for 1/3–1/2 of its length. Corolla (14–)15–22 mm long (spur excluded), pale-violet to pinkish, rarely almost white, with violet veins in the tube; upper lip scarcely darker, with lobes obovate to \pm broadly oblong, obtuse; lower lip

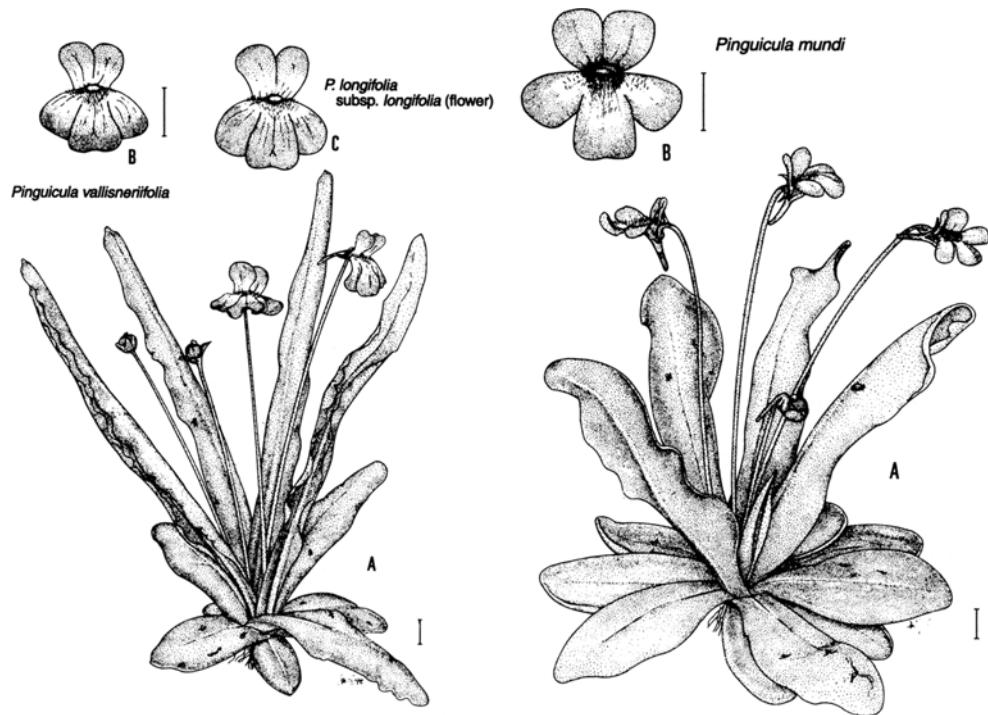

Fig. 5. *Pinguicula vallisneriifolia* and *Pinguicula mundi*; A – habit, B – flower. *P. longifolia* subsp. *longifolia*; C – flower. Scale bars 1 cm.

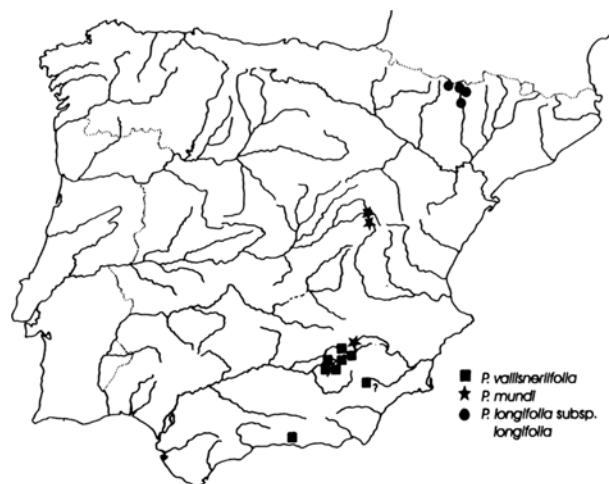

Fig. 6. Distribution map of *Pinguicula vallisneriifolia*, *P. longifolia* subsp. *longifolia* and *P. mundi*.

with lobes 6–13 mm long, longer than wide, obovate-oblong, overlapping, obtuse, coloured only in the upper part, the middle yellow-spotted near the base; throat white; tube very short, broadly infundibuliform, sparsely glandular outside; spur (9–)11–18 mm, cylindric-subulate or subulate, straight or slightly curved. Capsule 3–5 mm, ovoid; seeds 0.7–0.9 mm long, clavate, reticulate.

Chromosome number

$2n=32$ (LÖVE & KJELLQVIST 1974, ZAMORA et al. 1996).

Distribution

Endemic to the south of the Iberian Peninsula. The main centre of distribution of this species (Fig. 6) is in the Sierra de Cazorla and adjacent Sierra de Segura (Province of Jaén); it has also been seen by the present authors in a part of the Sierra de Segura, the river Tus, that is on the Province of Albacete side of the Jaén-Albacete border. There is also a disjunctive location in the Sierra de Cádiz (Province of Granada).

Ecological behaviour

Calcareous rock outcrops and at the feet of calcareous rocky outcrops, cave entrances, often in shady places. Calcicolous. Altitude: 600–1700 m. Flowering season: (IV–)V–VI(–VII).

Comments

The size, shape and colour of the corolla vary considerably in this species, following a north-south variation gradient in the Sierra de Cazorla and Sierra de Segura. The flowers of the northernmost populations are smaller and paler in colour, sometimes nearly white and even with no dark veins, whereas the flowers of the southernmost populations are larger, with a greater relative difference in size of the upper and lower petals, more brightly coloured and contrasted, and dark-veined (HERRERA et al. 1994).

The variability of this species has often caused it to be confused with other species described recently. Many of the citations made to date actually correspond to *P. mundi* and *P. dertosensis*, so the real distribution area of this taxon is far more limited than has often been thought.

6. *Pinguicula longifolia* RAMOND ex DC.

P. longifolia RAMOND ex DC. in LAM. et DC., Fl. Fr. ed. 3, 3: 728, 1805

Lectotype (**designated here**): Rochers du Port de Pinède (1797 M. RAMOND BBF 001442 left specimen!). Lectosyntype: Vallée d'Ordesa (1802 M. RAMOND BBF 001442 right specimen!).

6.1. *Pinguicula longifolia* RAMOND ex DC. subsp. *longifolia* (Fig. 5C)

Description

Perennial herbs, with slender roots and stolons present, overwintering as a bud. Leaves suberect to erect, petiolate or subsessile, with prominent median nerve on the back, with the margin not involute; spring leaves (at anthesis) (2.5–)3–6.5(–8) × 1.5–2.5(–2.8) cm, obovate to elliptic; summer leaves (at fruiting) 4–10, longer, 7–17(–20) × 1.2–2.5 cm, lanceolate to linear-lanceolate, undulate in the margins, obtuse or subacute. Pedicels 1–7, (5–)6–16(–17) cm long, glandular-pubescent. Upper lip of the calyx with lobes (3–)4–6 mm long, oblong to linear-oblong, obtuse or subacute; lower lip lobed for 1/2 of its length or sometimes nearly to the base. Corolla 18–27 mm long (spur excluded), violet, with veins in the tube; upper lip

scarcely darker, with lobes obovate to broadly oblong, obtuse; lower lip with lobes (7–)8–15 mm long, longer than wide, obovate-oblong, overlapping, obtuse, coloured in the upper 2/3, the middle one yellow-spotted near the base; throat white; tube very short, broadly infundibuliform, sparsely glandular outside; spur (9–)10–16(–18) mm, cylindric-subulate, straight or somewhat curved. Capsule 4–5.5 mm, ovoid-subglobose; seeds 0.7–0.9 mm long, clavate, reticulate.

Chromosome number

2n=32 (DOULAT 1947, CASPER 1962, 1963, ZAMORA et al. 1996).

Distribution

Pinguicula longifolia is distributed in the mountainous regions of southern Europe, from the central part of southern France to the central Pyrenees (Spain) and central Apennines (Italy). It has three subspecies: subsp. *longifolia*, which is endemic to the Iberian Peninsula (central Pyrenees, Province of Huesca; Fig. 6); subsp. *caussensis* CASPER, from the central part of southern France, characterized by its smaller corolla (22–35 mm, spur included); and subsp. *reichenbachiana* (SCHINDL.) CASPER, from the mountains of northern and central Italy and south-eastern France, which is distinguished by the lobes of the upper lip of the calyx being linear, and by having sometimes more than 3 ones.

Ecological behaviour

Similar to *P. vallisneriifolia*. Altitude: (640–)900–2000 m. Flowering season: V–VII.

Comments

This species is closely related to *P. vallisneriifolia*, although no confusion between the two has occurred, since they are geographically isolated from each other (Fig. 6). This species, like *P. vallisneriifolia*, shows considerable morphological variation, as noted by GARCÍA & ANTOR (1992).

7. *Pinguicula mundi* BLANCA et al. (Fig. 5)

P. mundi BLANCA, JAMILENA, RUÍZ-REJÓN et ZAMORA, Pl. Syst. Evol. 200: 58, 1996.

Holotype: In orto fluminis Mundo, loco dicto Cueva de los Chorros, Sierra del Calar del Mundo, pr. Riópar (Albacete provincia, Hispania), 1200 m s.m. alt. (15.VI.1993 R. ZAMORA GDAC 37729!).

— *P. vallisneriifolia* auct. p.p., non WEBB 1853.

Description

Perennial herbs, with slender roots and stolons present, overwintering as a bud. Leaves 6–12(–15), suberect to erect, sessile, with prominent median nerve on the back, with the margin not involute, slightly undulate; spring leaves (at anthesis) 3–6 × 1.5–2.5 cm, elliptic to obovate-oblong; summer leaves (at fruiting) longer, 6–11 × 1.5–3 cm, elliptic to obovate. Pedicels 1–10, 5–12 cm long, glandular-pubescent. Upper lip of the calyx with lobes 2.5–3.5 mm long, triangular-obtuse or slightly elliptic, obtuse or subacute; lower lip lobed for up to 1/2 of its length. Corolla (12–)14–21(–23) mm long (spur excluded), violet, sometimes with weakly-marked veins; upper lip dark violet, with lobes suborbicular to obovate, obtuse; lower lip with lobes 6–12 mm long, longer than wide, obovate, overlapping, obtuse, coloured only in the upper half, the middle one white- to yellow-spotted near the base; throat dark violet, except in the middle lobe of the lower lip; tube short, broadly infundibuliform, sparsely

glandular outside; spur (8–)9–14(–15) mm, cylindric-subulate, straight, sometimes slightly bifid. Capsule 3–5 mm, ovoid to subglobose; seeds 0.8–1 mm, narrowly ellipsoidal, reticulate.

Chromosome number

$2n=48$ (ZAMORA et al. 1996). *P. mundi* very probably has an allopolyploid origin, as ZAMORA et al. (1996) stated, from the crossing of a tetraploid species ($2n=32$, probably *P. vallisneriifolia*) with a diploid one ($2n=16$), and the subsequent duplication of the chromosome number.

Distribution

Endemic to the Iberian Peninsula: Serranía de Cuenca (Province of Cuenca and SE of the Province of Guadalajara); Sierra de Alcaraz and Sierra de Calar del Mundo (Province of Albacete). The distribution area of this species (Fig. 6) has been widened considerably in the most recent studies made, since when it was described it was considered to be restricted to the headwaters of the Mundo River (with a single place of occurrence, ZAMORA et al. 1996: 57).

Ecological behaviour

Bryocormophyte communities on calcareous banks and outcrops. Altitude: 900–1600 m. Flowering season: (V–)VI–VII.

Comments

This species was previously confused with *P. vallisneriifolia*, since it also has suberect leaves, with an undulated margin, which grow for a considerable time after anthesis. However, there are notable differences in the chromosome number and the elliptic to obovate summer leaves of *P. mundi*, which have a slightly undulate margin, and also the dark violet throat of the corolla, whereas *P. vallisneriifolia* has summer leaves ligulate with the margin markedly undulate and throat of the corolla white.

Subgen. *Micranthus* CASPER, Feddes Report. 66: 41, 1962

Roots stout. Overwintering as a bud. Flowers small. Corolla white, with yellow spots in the throat; corolla-lobes entire; spur curved. Capsule pear-shaped, somewhat over twice the length of the calyx.

8. *Pinguicula alpina* L. (Fig. 7)

P. alpina L., Sp. Pl. 17, 1753.

Ind. loc.: "Habitat in Alpibus Lapponicis".

Lectotype (BLANCA & JARVIS, designated here): Although there is a specimen labelled as *P. alpina* in LINN (sheet 33.2!), the annotations seem to not be by Linnaeus and it does not appear to be original material for the name. There is an original specimen in the Lapland herbarium in the Institut de France, Paris!; this is in rather poor condition. Linnaeus took his diagnosis from his *Flora lapponica* account (LINNAEUS 1737), where there is an illustration (t. 12, f. 3), which is here selected as the lectotype.

Description

Perennial herbs with brownish, long and relatively thick roots, overwintering as a bud, without stolons. Leaves 5–8, horizontal, close to the soil, sessile, the margin involute; spring leaves (at anthesis) 1.5–3 × 0.5–1 cm, oblong-elliptic to oblong-lanceolate, yellowish-green; summer leaves (at fruiting) similar to spring leaves. Pedicels 1–4(–5), 4–10 cm long, glabrous

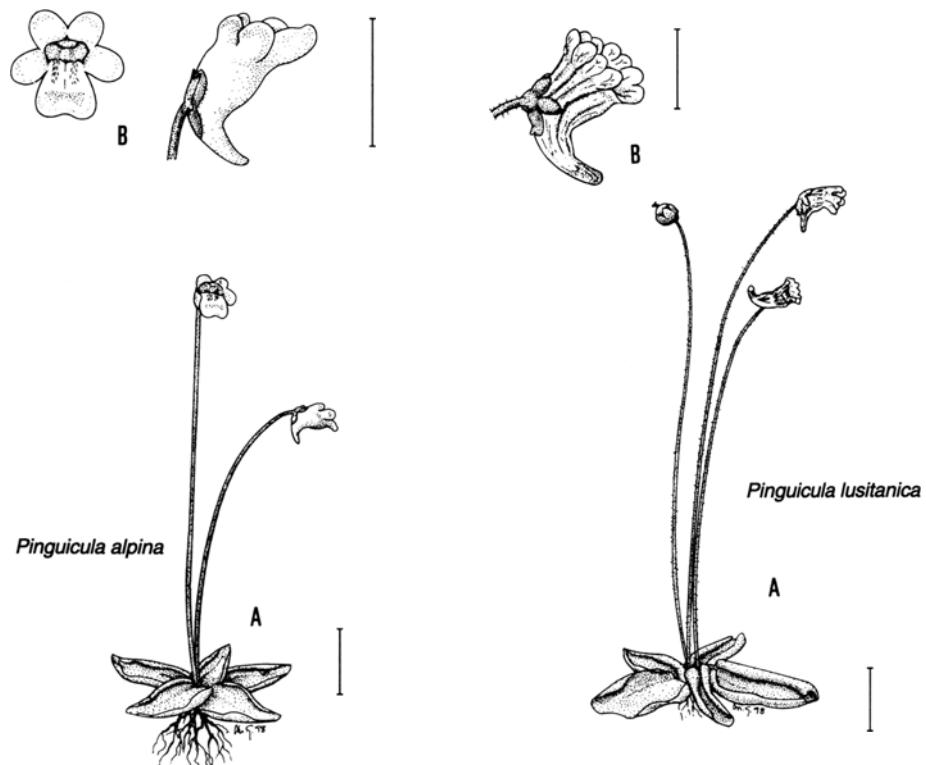

Fig. 7. *Pinguicula alpina*; A – habit, B – flower. Scale bars 1 cm. *Pinguicula lusitanica*; A – habit, B – flower. Scale bar: A – 1 cm, B – 0.5 cm.

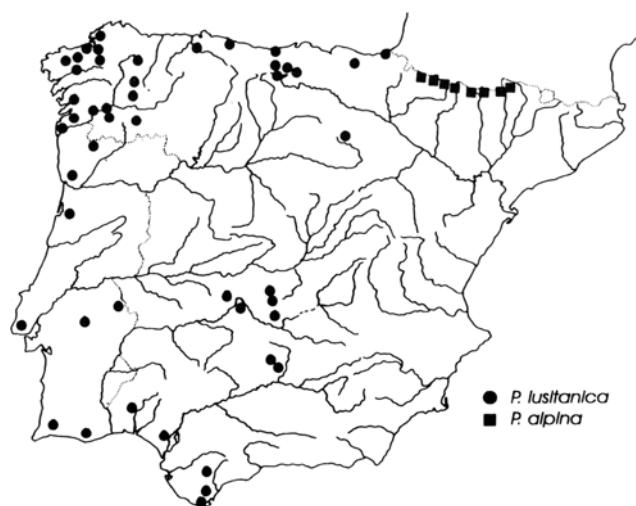

Fig. 8. Distribution map of *Pinguicula alpina* and *P. lusitanica* in the Iberian Peninsula.

or sparsely glandular principally in the top. Calyx glabrescent; lobes of the upper lip 2.2–2.7(–3) mm long, triangular to ovate, obtuse or subacute, scarcely divergent; lower lip lobed for up to 1/3 of its length, lobes not divergent. Corolla 7–11(–12) mm (spur excluded), white, with yellow spots at the throat, lips markedly unequal; upper lip shorter, with lobes suborbicular, obtuse; lower lip with lobes not overlapping, the middle one 4–6(–7) mm, much longer than lateral ones, with apex obtuse or truncate; tube short, broadly infundibuliform, glabrescens outside; spur 2–3(–4) mm, conoidal or subcylindrical, obtuse, curved, yellowish. Capsule 6–7 mm long, pear-shaped, acute, longer than the calyx; seeds 0.7–0.8 mm long, oblong, rugose-striate or obscurely reticulate.

Chromosome number

2n=32 (LÖVE & LÖVE 1944, 1956, DOULAT 1947, WOOD & GODFREY 1957, CASPER 1962, 1963, MURÍN et al. 1980).

Distribution

Mountainous and alpine regions of Eurasia. In the Iberian Peninsula it is only present in the central Pyrenees (Provinces of Navarra, Huesca and Lérida; Fig. 8).

Ecological behaviour

Damp and shady places, waterlogged pastures, banks of streams, etc. Calcicolous. Altitude: 1800–2700 m. Flowering season: VII–VIII.

Subgen. *Isoloba* BARNHART, Mem. New York Bot. Gard. 6: 51, 1916

Roots slender. Overwintering as a rosette. Flowers small. Corolla pale lilac to pinkish, with lips subequal and lobes all emarginate; spur deflexed. Capsule subglobose, scarcely larger than the calyx.

9. *Pinguicula lusitanica* L. (Fig. 7)

P. lusitanica L., Sp. Pl. 17, 1753. Ind. loc.: “Habitat in Lusitania”.

Neotype (BLANCA & JARVIS, designated here): Habitat in arenosis humidis pr. S. Gens, Sta Cruz do Bispo, circa Porto (V.1883 E. JOHNSTON – Flora lusitanica exsiccata no. 2662, Herbario A.A. de Carvalho Monteiro, BM!).

There seem to be no original elements for this name, with no specimens traceable, and only a brief description, without any illustration. Therefore a neotype had to be selected.

Description

Perennial herbs with slender roots, overwintering as a rosette, without stolons. Leaves 5–12, horizontal, close to the soil, shortly petiolate, sometimes with petiole up to 1/2 of the limb, the margin strongly involute; spring leaves (at anthesis) (0.7–)1–3(–3.5) × 0.3–0.9(–1) cm, oblong to oblong-ovate, sometimes elliptic or obovate, greyish, with purple veins; summer leaves (at fruiting) similar to spring leaves. Pedicels 1–6(–8), (3–)4–20(–25) cm long, very slender, glandular-pubescent principally in the upper part. Upper lip of the calyx with lobes (1.5–)2–4 mm long, ovate, obtuse or subacute, strongly divergent; lower lip lobed for up to 1/3 of its length, lobes scarcely divergent. Corolla 5–9 mm long (spur excluded), pale lilac to pinkish with marked veins, yellow at the throat; lips subequal, with lobes 1.5–3.5 mm, not overlapping, suborbicular and emarginate; tube cylindrical, longer than the lobes; spur 2.5–4.5(–5) mm, subcylindrical, sometimes enlarged in the apex, obtuse, deflexed, yellowish.

Capsule 2.5–4.5 mm long, subglobose; seeds 0.5–0.6 mm long, oblong to narrowly ellipsoidal, prominently reticulate.

Chromosome number

2n=12 (CONTANDRIOPoulos 1962, KONDO 1969, SCHOTSMAN 1970).

Distribution

Western Europe (British Isles, France, Spain and Portugal) and north-west Africa (Morocco). In the Iberian Peninsula it is distributed throughout the western half (Fig. 8).

Ecological behaviour

Peat bogs, waterlogged places, banks, etc. Silicicolous. Altitude: 10–1200 m. Flowering season: IV–VIII.

Acknowledgements: We are extremely grateful to M. Ángeles Goicoechea for the drawings of the species; to the curators of the herbaria BBF, BC, BM, FI, GDA, GDAC, JACA, MA, MAF, MGC, P, SALA and SEV for the loan of specimens; to P. Mayoux and J. Jolinon, for their special assistance in the typification of the species names; and to R. Howard for revising the English-language manuscript. The research project was supported by the Dirección General de Investigación Científica y Técnica (Spanish Scientific and Technical Research Directorate [DGICYT], via grant PB95-1218).
